* MDL's based on authentic standards; other compounds estimated from closest related compound.

MDL Determinations

Sediment Matrix

Sediment was acquired from GERG's Geochemical Prospecting archives. Oven dried sediment from the Gulf of Mexico was pre-extracted by Soxhlet extraction for four hours with methylene chloride three times. The extracted sediment was thoroughly homogenized and seven aliquots of 15.0 grams were taken. Since this sediment was dry, 15 mL of HPLC grade water was added to each and thoroughly homogenized to simulate wet sediment. These aliquots were then fortified with the spike solution to yield final extract concentrations of ~3 ppb for PHC's and ~6 ppb for PAH's on a dry weight basis. These values are selected to be between 1 and 5 times the MDL based on historical data. Samples were extracted and purified according to the GERG SOP-8902. The final volume of extract was reduced to 1.0 mL.

The MDL's for all peaks in the spiking solution were calculated according to the procedures outlined in the Federal Registry (Vol. 49, No 209). The MDL for an analyte is the standard deviation of the seven replicates times the student's *t* value (2.681) for a one-tailed test at the 99% confidence level with n-1(6) degrees of freedom. For compounds not in the spiking solution and not found in the actual matrix at required levels, MDLs were estimated. Dibenzothiophene (DBT) was not available. Therefore the MDL levels for phenanthrene was used. For alkylated PAH homologues, MDL's were estimated as twice that of a similar authentic compound. Homologue clusters can contain a number of isomers complicating the determination of the MDL. The MDL for C_2-naphthalenes is assumed be twice the MDL for 2,6-dimethylnaphthalene (0.6*2=1.2). If no standard was available for a given alkylation, the nearest alkylated homologue or parent was used. For example, the MDL for alkylated dibenzothiophenes, was assumed to be twice that for DBT. Since both isomers of the C_1-naphthalenes are present in the spike solution, the MDL for these data was assumed to be two times the average of the MDL's for 1-methyl and 2-methylnaphthalene. For C_1-fluoranthenes and pyrenes, the MDL was assumed to be 2 times the average MDL for fluoranthene and pyrene.

Tissue Matrix

Fresh oyster tissue was purchased from a local market. The tissue was thoroughly homogenized and seven aliquots of 10.0 gram wet weight were taken. These aliquots were fortified with the spike solution to yield final extract concentrations of ~3 ppb for PHC's and ~6 ppb for PAH's on a wet weight basis. These values are selected to be between 1 and 5 times the estimated MDL based on historical data. Analyte levels greater than 10 times the MDL were not used to calculate to the MDLs by definition. Samples were extracted and purified according to the GERG SOP-8903. Percent moisture was determined for the tissue as outlined in GERG SOP-8903. The extracts were then sent to the analytical lab for analysis, using

GERG SOP-8904 for PHC's and GERG SOP-8905 for PAH's. Analyte concentrations were calculated on a dry weight basis.

The MDL's (Tables 3 & 4) for all target analytes were calculated according to the procedures outlined in the Federal Registry (Vol. 49, No 209). The MDL for an analyte is the standard deviation of the seven replicates times the student's *t* value (2.681) for a one-tailed test at the 99% confidence level with n-1(6) degrees of freedom. For compounds not in the spiking solution and not found in the actual matrix, MDLs were estimated. Dibenzothiophene was not available. Therefore the MDL levels for phenanthrene was used. For alkylated PAH homologues, MDL's were estimated as twice that of a similar authentic compound. Homologue clusters can contain a number of isomers complicating the determination of the MDL. The MDL for C_2-naphthalenes is assumed be twice the MDL for 2,6-dimethylnaphthalene (8.3*2=16.5). If no standard was available for a given alkylation, the nearest alkylated homologue or parent was used. For example, the MDL for alkylated dibenzothiophenes, was assumed to be twice that for DBT. Since both isomers of the C_1-naphthalenes are present in the spike solution, the MDL for these data was assumed to be two times the average of the MDL's for 1-methyl and 2-methylnaphthalene. For C_1-fluoranthenes and pyrenes, the MDL was estimated as 2 times the average MDL for fluoranthene and pyrene.
